### Can Quantum-Mechanical Description of Physical Reality Be Considered Complete?

A. EINSTEIN, B. PODOLSKY AND N. ROSEN, *Institute for Advanced Study, Princeton, New Jersey*

(Received March 25, 1935)

In a complete theory there is an element corresponding to each element of reality. A sufficient condition for the reality of a physical quantity is the possibility of predicting it with certainty, without disturbing the system. In quantum mechanics in the case of two physical quantities described by non-commuting operators, the knowledge of one precludes the knowledge of the other. Then either (1) the description of reality given by the wave function in

quantum mechanics is not complete or (2) these two quantities cannot have simultaneous reality. Consideration of the problem of making predictions concerning a system on the basis of measurements made on another system that had previously interacted with it leads to the result that if (1) is false then (2) is also false. One is thus led to conclude that the description of reality as given by a wave function is not complete.

#### 1.

ANY serious consideration of a physical theory must take into account the distinction between the objective reality, which is

Whatever the meaning assigned to the term *complete*, the following requirement for a complete theory seems to be a necessary one: *every element of the physical reality must have a counter-*

# EPR paradox II

Paper by Einstein, Podolsky, and Rosen (EPR), Phys. Rev. 1935.

- The paper considered two particles in a singlet state

$$|\psi_{\text{singlet}}\rangle = \frac{1}{\sqrt{2}}(|01\rangle - |10\rangle).$$

- Let us call the two parties A and B (Alice and Bob).
- Some simple measurement scenarios are the following

Alice	Bob
$z = +1$	$z = -1$
$z = -1$	$z = +1$
$x = +1$	$z = \pm 1$

# EPR paradox III

Questions:

- How does Bob's particle know, what Alice measured?
- The outcome is random in some cases. We should be able to determine the outcome of the measurement. Is not physics deterministic?
- Maybe, we just do not have enough information. There can be sofar unknown elements of reality that determine the measurement outcome.

## 1 Bell inequalities

- Motivation
- A. EPR paradox
- B. Local hidden variable models
- C. The CHSH Bell inequality
- D. Mermin's inequality
- E. Loopholes
  - Detection efficiency loophole
  - Locality loophole

# Local hidden variable models

- Do the measured quantities correspond to an element of reality before the measurement? Let us assume that they do. (Reality)
- Assume that no faster than light communication is possible. (Locality).

**Figure:**

Bipartite quantum system. We measure  $A_1$  and  $A_2$  at party A, and measure  $B_1$  and  $B_2$  at party B.

## Local hidden variable models II

- Assume that we measure  $A_1$  and  $A_2$  at party  $A$ , and measure  $B_1$  and  $B_2$  at party  $B$ . Both  $A_k$  and  $B_k$  have  $\pm 1$  measurement results.
- $A_k$  and  $B_k$  are quantum mechanically incompatible.
- Let us assume that all the four measurement outcomes exist before the measurement.
- The idea is that at each measurement  $k$ , there are  $a_{1,k}$ ,  $a_{2,k}$ ,  $b_{1,k}$ ,  $b_{2,k}$  available.
- We will show that quantum mechanics is not like that.

# Local hidden variable models III

- We expect a measurement record like the following:

$k$	$a_{1,k}$	$a_{2,k}$	$b_{1,k}$	$b_{2,k}$
1	+1	-1	+1	+1
2	-1	+1	+1	-1
3	+1	+1	-1	+1
4	-1	-1	+1	-1
5	+1	+1	+1	-1
6	-1	-1	-1	+1
...	...	...	...	...

- **Red color** indicates the measured values. The other values we cannot check, we can only assume that they were there.

## Local hidden variable models IV

- The correlations can be obtained as

$$\langle A_m B_n \rangle = \frac{1}{M} \sum_{k=1}^M a_{m,k} b_{n,k}.$$

- Here,  $k$  is the *hidden variable*. If I knew  $k$ , I could tell the outcome. It is hidden, but it is there somewhere.

# Local hidden variable models V

- Usual formula, with  $\lambda$  as a hidden variable for probabilities of outcomes for the discrete case

$$p(\mathbf{a}_i^\alpha, \mathbf{b}_j^\beta) = \int d\lambda p(\lambda) \mathcal{A}_\lambda(\mathbf{a}_i^\alpha) \mathcal{B}_\lambda(\mathbf{b}_j^\beta),$$

Continuous case:

$$f(\mathbf{a}_m, \mathbf{b}_n) = \int f_{m,\lambda}(\mathbf{a}_m) g_{n,\lambda}(\mathbf{b}_n) d\lambda$$

Here  $f$ 's and  $g$ 's are probability density functions.

- In words: all two-variable probability distributions can be given as a sum of product distributions.

## 1 Bell inequalities

- Motivation
- A. EPR paradox
- B. Local hidden variable models
- C. The CHSH Bell inequality
- D. Mermin's inequality
- E. Loopholes
  - Detection efficiency loophole
  - Locality loophole

# The CHSH Bell inequality

- Let us consider the following expression:

$$A_1 B_1 + A_2 B_1 + A_1 B_2 - A_2 B_2.$$

- Let us now substitute  $+1$  or  $-1$  to  $A_k$  and  $B_k$ . There are 16 combinations. We obtain

$$A_1 B_1 + A_2 B_1 + A_1 B_2 - A_2 B_2 \leq 2$$

- But, if we identify  $A$  with  $\sigma_x$  and  $B$  with  $\sigma_y$ , then there is a quantum state for which

$$\langle \sigma_x \otimes \sigma_x + \sigma_y \otimes \sigma_x + \sigma_x \otimes \sigma_y - \sigma_y \otimes \sigma_y \rangle = 2\sqrt{2}.$$

This state is, apart from local transformations, the singlet  $|01\rangle - |10\rangle$ . **How is this possible?**

# The CHSH Bell inequality II

- The real measurement record is the following:

$k$	$a_{1,k}$	$a_{2,k}$	$b_{1,k}$	$b_{2,k}$
1	+1	...	+1	...
2	-1	...	...	-1
3	...	+1	-1	...
4	-1	...	+1	...
5	...	+1	...	-1
6	-1	...	-1	...
...	...	...	...	...

- The correlations can be obtained as

$$\langle A_m B_n \rangle = \frac{1}{|\mathcal{M}_{m,n}|} \sum_{k \in \mathcal{M}_{m,n}} a_{m,k} b_{n,k},$$

where  $\mathcal{M}_{m,n}$  contains the indices corresponding to measuring  $A_m$  and  $B_n$ . This is the reason that correlations do not fit an LHV model.

# Summary of Bell inequalities

- **Bell inequalities** are made for bipartite (or multipartite systems).
- At each party, we measure one of two (or more) operators, such as  $\sigma_x$  and  $\sigma_y$ .
- Bell inequalities are inequalities with correlation terms that are constructed to exclude LHV models.
- They have the form

$$\langle B \rangle \leq C,$$

where  $B$  is the Bell operator and  $C$  is a constant.

## Summary of Bell inequalities II

- **$C$  is the classical maximum.**  $C$  is obtained from maximizing the operator  $B$  for all cases when we replace the operators with the measurement results. E.g., we replace  $\sigma_x$  with  $+1$  or  $-1$ . In this way we obtain the maximum assuming
  - **Reality:** All outcomes of all measurement results exist before the measurements.
  - **Locality:** Alice does not know what Bob measures.
- If for a quantum state  $|\Phi\rangle$  we have  $\langle B \rangle_\Phi > C$  then we say that the Bell inequality is violated by the quantum state.
- We can also say that the measurement results cannot be described by an LHV model.

## Summary of Bell inequalities III

- The points corresponding to correlations fulfilling Bell inequalities are within a **polytope**. Extreme points have correlations  $\pm 1$ .

## 1 Bell inequalities

- Motivation
- A. EPR paradox
- B. Local hidden variable models
- C. The CHSH Bell inequality
- D. Mermin's inequality
- E. Loopholes
  - Detection efficiency loophole
  - Locality loophole

# Mermin's inequality

For  $N$  qubits, the **Mermin inequality** is given by

$$\langle X_1 X_2 X_3 X_4 X_5 \cdots X_N \rangle - \sum_{\pi} \langle Y_1 Y_2 X_3 X_4 X_5 \cdots X_N \rangle \\ + \sum_{\pi} \langle Y_1 Y_2 Y_3 Y_4 X_5 \cdots X_N \rangle - \dots + \dots \leq L_{\text{Mermin}},$$

where  $\sum_{\pi}$  represents the sum of all possible permutations of the particles that give distinct terms.  $X_k, Y_k \in \{-1, +1\}$ .  $L_{\text{Mermin}}$  is the maximum for local states. It is defined as

$$L_{\text{Mermin}} = \begin{cases} 2^{N/2} & \text{for even } N, \\ 2^{(N-1)/2} & \text{for odd } N. \end{cases}$$

- The quantum maximum is  $2^{N-1}$  (all terms are  $+1$ ).

## Mermin's inequality II

- The state maximally violating the Mermin inequality is the GHZ state.
- The GHZ state is defined as

$$|\text{GHZ}\rangle = \frac{1}{\sqrt{2}} (|00\dots 00\rangle + |11\dots 11\rangle).$$

- For the GHZ state we can identify  $X_k$  and  $Y_k$  with the Pauli spin matrices  $\sigma_x$  and  $\sigma_y$ .

## Mermin's inequality III

- Example for  $N = 3$  qubits. The Mermin inequality is given as

$$\langle X_1 X_2 X_3 \rangle - \langle Y_1 Y_2 X_3 \rangle - \langle Y_1 X_2 Y_3 \rangle - \langle X_1 Y_2 Y_3 \rangle \leq 2.$$

- Then, for the GHZ state we get 4 on the left-hand side, since for the GHZ states

$$\langle X_1 X_2 X_3 \rangle - \langle Y_1 Y_2 X_3 \rangle - \langle Y_1 X_2 Y_3 \rangle - \langle X_1 Y_2 Y_3 \rangle = 4,$$

since

$$\langle \sigma_x \otimes \sigma_x \otimes \sigma_x \rangle = +1,$$

$$\langle \sigma_y \otimes \sigma_y \otimes \sigma_x \rangle = -1,$$

$$\langle \sigma_y \otimes \sigma_x \otimes \sigma_y \rangle = -1,$$

$$\langle \sigma_x \otimes \sigma_y \otimes \sigma_y \rangle = -1.$$

## 1 Bell inequalities

- Motivation
- A. EPR paradox
- B. Local hidden variable models
- C. The CHSH Bell inequality
- D. Mermin's inequality
- E. Loopholes
  - Detection efficiency loophole
  - Locality loophole

# Detection efficiency loophole

- Only very small part of the photons are detected by a detector. (The detector efficiency is typically much below 100%.)
- Maybe, only the statistics of the detected events violate the Bell inequalities.
- If we knew the statistics of all events, we would not get a Bell inequality violation.
- Typically problem with photons.

# Locality loophole

- For each Bell inequality, at each party one of at least two operators is measured.
- If one party might know what is measured at the other party, some unknown mechanism could still mimic the violation of the Bell inequalities by communicating between the parties.
- Typically problem with trapped cold ions.

## Recent loophole free experiments

- Loophole free experiments are difficult, thus they have been carried out only recently.
